MOURNING DOVE STATUS REPORT 1964

UNITED STATES DEPARTMENT OF THE INTERIOR
FISH AND WILDLIFE SERVICE
BUREAU OF SPORT FISHERIES AND WILDLIFE
Special Scientific Report--Wildlife No. 87

The Department of the Interior, created in 1849, is a Department of Conservation, concerned with management, conservation, and development of the Nation's water, wildlife, fish, mineral, forest, and park and recreational resources. It has major responsibilities also for Indian and Territorial affairs.

As America's principal conservation agency, the Department works to assure that nonrenewable resources are developed and used wisely, that park and recreational resources are conserved for the future, and that renewable resources make their full contribution to the progress, prosperity, and security of the United States, now and in the future.

ABSTRACT

An index to the 1964 mourning dove breeding population was obtained by a call-count survey conducted throughout the United States. Trends in the breeding population index were calculated for three management units and for hunting and nonhunting States within the management units. Trends in the breeding population indexes from 1963 to 1964 were as follows: Eastern Unit up 7.4 percent, Central Unit up 3.6 percent, and Western Unit up 18.7 percent. For the United States as a whole, the 1964 breeding population was up 7.9 percent from 1963.

Summaries of call-count surveys conducted in Canada during 1963 and 1964 are included. The average number of doves heard on comparable routes in Ontario (the only Province submitting comparable data) declined 3.9 percent from the 1963 level.

INTRODUCTION

An annual survey of the breeding population of mourning doves by a system of call-count routes provides an index to the status of the dove population in the United States. Through the cooperation of State, Federal, and independent observers, call-count routes were widely established by 1953. The hundreds of cooperators who participate in the call-count survey have contributed to data that form the basis for this report.

Prior to 1960, the annual status of the mourning dove population was reported in the <u>Mourning Dove Newsletter</u>. The <u>Newsletter</u> has been discontinued, but the annual status of the population has been published annually in the Special Scientific Report--Wildlife Series since 1960. The 1960 through 1963 reports are numbered 49, 57, 70, and 73, respectively.

In 1961, dove-call routes were set up and run on a trial basis in several Canadian Provinces. Results of these trial routes emphasized the desirability of establishing and maintaining a dove-call census in Canada.

The Canadian dove-call census was conducted again in 1963 and 1964, and the results of the censuses for those years are set forth in table 5.

It is expected that with the establishment of additional routes, the compilation of sufficient comparable data, and the incorporation of suitable weighting factors, the data provided by the Canadian cooperators will prove extremely valuable in future management of the mourning dove.

The call-count survey is conducted each year during the period May 20-June 10. Intensive studies conducted in the Eastern United States (Special Scientific Report--Wildlife No. 17, 1952) indicate that dove calling activity is relatively stable during this period.

In order to provide for the required publication of hunting regulations, the Dove Regulations Committee must

meet no later than late June. Status statistics must be summarized for consideration by this Committee. The annual Status Report (or a preliminary version thereof) serves this purpose. The Status Report is also distributed to all cooperators and is available to interested organizations and individuals.

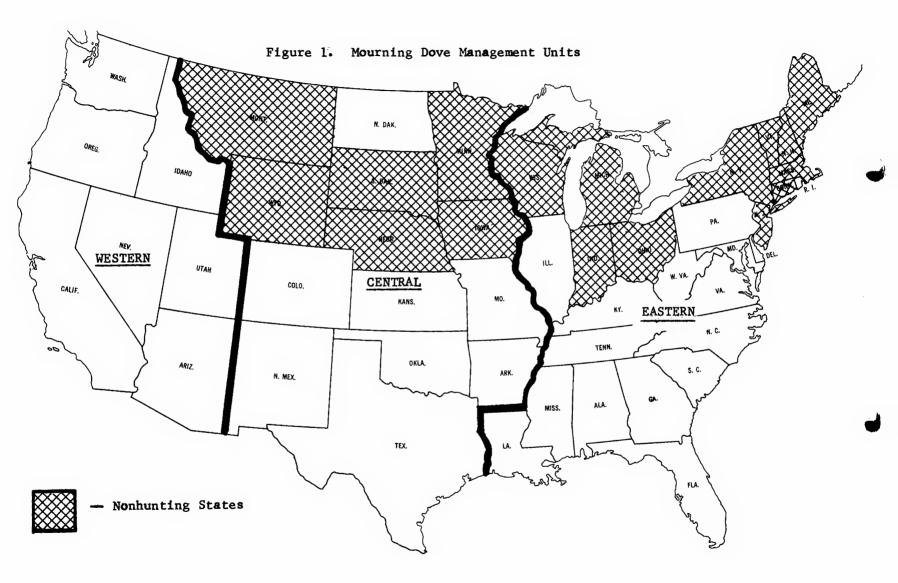

For several years prior to 1960, the Federal framework of mourning dove hunting regulations was established on the basis of eastern and western groups of States. Recent analysis of banding data indicates that there are three largely independent units of the mourning dove population (Kiel, 1959). Since 1960, the Federal framework of hunting regulations has been based on these three management units. The criteria for a management unit are that the bulk of the doves harvested within a unit is produced within that same unit and that a significant number of doves produced within a unit is not harvested outside that unit. The Eastern, Central, and Western Management Units, outlined in figure 1, best meet these criteria. In order to establish more firmly the management unit boundaries, additional analysis of banding data is currently in progress.

PROCEDURE

The call-count method

Call-count routes were established after field investigations in 1950-51 demonstrated the feasibility of the technique. These investigations were reported by Foote, Peters, McGowan, Kerley, Duvall, Robbins, and Wagner (1952). Each route is 20 miles long and has 20 listening stations located 1 mile apart. Call-counts begin one-half hour before sunrise and continue for 2 hours. A record is kept during the survey period of all doves seen or heard calling along the survey route. Information on the call-count method and procedures for randomly selecting call-count routes was presented by Foote, Peters, and Finkner (1958).

The only currently available dove population index, national and international in scope, is the call-count survey. The survey has limitations and possible biases which require further study. One important limitation is the fact that the survey provides an index to the breeding population and does not take

production into consideration. This limitation is especially noteworthy since a high percentage of an average fall population is composed of young-of-the-year.

As a basis for breeding population indexes, it has been found that doves heard calling have provided a less variable index than doves seen. Recent studies (Frankel and Baskett, 1961 and Jackson and Baskett, 1964) have shown that unmated males call at a greater rate than mated males. This suggests that the annual call-count census measures changes in the ratio of mated males to unmated males, rather than changes in breeding dove densities. However, Wight (in press) shows that changes in matedness, where the sex ratios of the adult segment of the population approach equality, will not significantly alter the capability of the dove call-count census to measure annual trends in the mourning dove breeding population. Continued research on this problem is being conducted at this time.

Weighting factors

When combining data from several States to obtain breeding population indexes for management units or parts of management units, it is necessary to give appropriate weight to the data from each State. This is done by multiplying the adjusted average number of doves heard calling per route in each State by the estimated area of dove habitat (in square miles) in the State to obtain a breeding population index value. These index values from each State are then added together to obtain the properly weighted breeding population index for the combination of States. This weighting procedure recognizes differences between States, both in dove density and in the amount of habitat. Dove habitat area was estimated and listed in the 1958 Mourning Dove Newsletter in table 1.

Randomization of dove-call routes

In order that the data on dove population density shall be representative of the breeding dove population of each State, random selection of dove census routes is desirable. The present management routes were, in some cases, selected in areas of high-density dove populations and do not yield representative measurements of the breeding dove populations throughout the entire State.

Randomly selected dove-call routes were first selected and run in the States of Alabama, Georgia, Kentucky, Mississippi, North Carolina, South Carolina, and Tennessee during the 1959 dove census. In 1961, the States of Arizona, California, Florida, Maryland, and Virginia also established and ran randomly selected dove census routes.

The States of Idaho, South Dakota, Wisconsin, Missouri, Kansas, Nebraska, and Minnesota established and censused randomly selected routes during 1963. This year's data, therefore, provide the first comparison of random routes in successive years for those States.

In 1964, in addition to the regular management routes, random routes were selected and run in the States of Colorado, Illinois, Iowa, Louisiana, Nevada, Ohio, Oregon, Utah, and Washington. These routes will be run again in 1965 and the comparable data will be incorporated into the 1965 Mourning Dove Status Report.

Long-term trends

A base year was selected for the purpose of showing longterm trends in a State's breeding dove population index. Annual percentage changes have been applied to the base figure (average doves heard calling per route) to give an adjusted figure which shows the true relation of indexes from year to year. The selection of a base figure is necessary because not all routes are censused each year.

The average number of doves heard calling on routes censused in two successive years in each State has been adjusted according to percentage change from the previous year. This procedure may be illustrated with data from Alabama where 1957 was selected as a base year (table 3). In that year, the average number of doves heard calling per route was 21.1. In 1958, the percentage change from 1957 in counts on comparable routes was an increase of 12.8 percent, so the base figure of 21.1 was adjusted upward by 12.8 percent to a level of 23.8. In 1959, the percentage change from 1958 in counts on comparable routes was a decrease of 21.6 percent. The 1958 "average heard" figure of 23.8 was, therefore, decreased 21.6 percent to the 1959 level of 18.7 percent.

TRENDS IN THE BREEDING POPULATION INDEX - 1964

Eastern Management Unit

The breeding dove population index for the Eastern Unit increased 7.4 percent from its 1963 level (table 1). This indicates a reversal of the general decline observed in the 1961, 1962, and 1963 surveys (figure 2). The 1964 index is 3.1 percent below the peak 1960 index and 2.9 percent above the Unit's 10-year average index (1954-1963).

The hunting States of the Eastern Unit showed an 11.5 percent increase from the 1963 breeding population index. The nonhunting States showed a 4.0 percent decline from the 1963 population index level (figure 3).

Central Management Unit

The breeding dove population index for the Central Unit increased 3.6 percent from the 1963 level (table 1). The increase for this Unit also follows a general decline from the peak index reached in 1960 (figure 2).

In hunting States of the Central Unit, the index increased 4.0 percent from its 1963 level. The index in the nonhunting States of the Central Unit showed an increase of 3.0 percent above the 1963 levels. Trends in breeding-population indexes are depicted in figure 3.

The Central Unit's 1964 index is 18.7 percent below the peak index reached in 1960 and is 2.2 percent below the 10-year average index (1954-1963).

Western Management Unit

The index for the Western Unit increased 18.7 percent from the 1963 level (table 1). The 1964 level is 3.4 percent below this Unit's peak population index, reached in 1959, and is 14.7 percent above the 10-year average index (1954-1963).

Figure 2. Trends in Breeding-population Indexes by Management Units

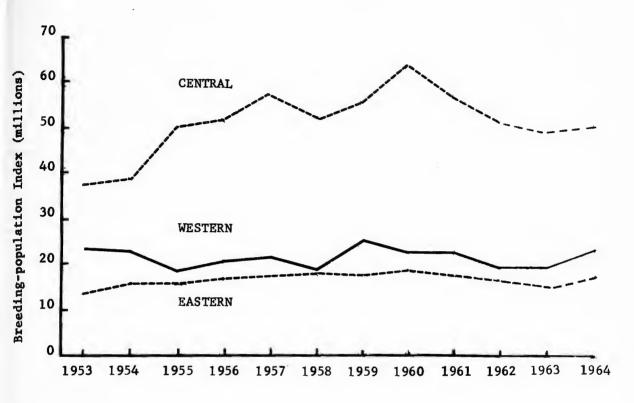

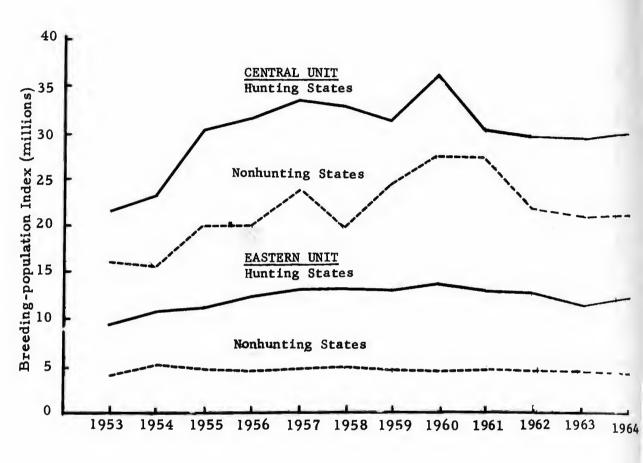

Figure 3. A Comparison of Trends in Breeding-population Indexes for Hunting and Nonhunting States within Management Units.

Discussion of population index trends

Breeding mourning dove population indexes for all management units increased this year from their 1963 levels. Despite a small decrease in the nonhunting States of the Eastern Management Unit, the entire Unit showed an increase and is presently above its 10-year average. This increase follows 3 years of decline from the peak 1960 index.

The indexes of both the hunting and nonhunting States of the Central Management Unit increased slightly over the 1963 levels. The entire Central Unit showed a 3.6 percent increase, which is also the first increase since 1960.

The largest increase in 1964 was in the Western Management Unit.

The 1964 breeding dove population index for the entire United States showed an increase of 7.9 percent over 1963. The current index is 2.7 percent above the 10-year average and 10.2 percent below the peak 1960 index.

To date, Ontario is the only Canadian Province which has provided comparable dove population status data. The average number of doves heard calling on comparable routes decreased slightly (3.9 percent) from the 1963 level in Ontario (table 2).

^{*} From a base year, average doves heard calling per route for each State has been adjusted annually according to the percentage change from the preceding year in counts on comparable routes. The index, expressed in thousands, is the product of the adjusted average doves heard per route and the estimated area of dove habitat.

^{**} The area of dove habitat has not been estimated for Maine, New Hampshire, Rhode Island, Vermont, or Canadian Provinces.

^{***} To date only Ontario has submitted comparable data for routes run in consecutive years.

Table 3.--Trends in the breeding-population index, 1957-64

The first figure listed for each State by years is the adjusted average doves heard calling per route. The method of adjustment is described in the text. The base year for adjustments was 1956 or 1957. States for which 1957 was the base year are those that reorganized call-count routes in that year. These States are Alabama, Georgia, Kentucky, Mississippi, North Carolina, South Carolina, and Tennessee.

The second figure for each State is the breeding-population index. The index, expressed in thousands, is the product of the adjusted average doves heard per route and the estimated area of dove habitat. (Habitat area is given in table 1).

Data for the years 1953 through 1956 may be obtained from Special Scientific Report--Wildlife No. 70.

^{*} Maine, New Hampshire, Rhode Island, and Vermont first established call-count routes in 1959. No estimate has been made of the square miles of dove habitat in these States.

Table 4.--Summary of call-count routes by States Includes all routes run in 1964, but only comparable routes for 1963 Route numbers followed by letter R indicate randomized routes
